The Hall Effect in Semiconductors

Zekeriya Gökhan Evelek Boğaziçi University • Physics Department

Abstract—In this experiment we have investigated the properties of the hall effect. We have first found the resistance of the hall probe. Then we have measured hall voltage and current at constant magnetic field, for both zero and nonzero field. Then we also measured the magnetic field and hall voltage at constant current, both at the same magnitude but different signs. Those measurements are used to determine Hall Coefficients and mobility of the electrons(we have used n-type semiconductor). The weighted average of Hall Coefficient was found out to be $R_H(weighted) = -0.00089 \pm 0.00012 \frac{m^3}{As}$ and of mobility of the electrons was found out to be $\mu_e(weighted) = -0.031 \pm 0.008 \frac{m^2}{V_s}$.

I. THEORY

Although the fact that the wire carrying current in a magnetic field experiences a force was known before, it was after Maxwell's systematization of electromagnetic theory that Edwin Hall discovered the hall effect. He has questioned if the magnetic field interacts with conductors and concluded that the magnetic force results in the separation of the current in the one side so that there appears a measaureable voltage. The interesting fact is that Edwin Hall discovered this effect years before the discovery of the electrons.[1]

Moving charged particles experiences a force and it is calculated by the famous Lorentz Force Law as follows:

$$\vec{F} = q(\vec{E} + \vec{v} \times \vec{B}) \tag{1}$$

where, q is the charge, E is the electric field, v is the velocity and B is the magnetic field.

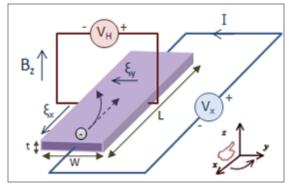

Fig. 1. Hall effect measurement setup for electrons [1]

As seen in the figure above, since in steady state F=0, then:

$$E_y + v_x B_z = 0 (2)$$

and

$$E_y = \frac{V_H}{w} \tag{3}$$

By combining the equations 2 and 3 we get the hall voltage as:

$$V_H = v_x B_z w \tag{4}$$

We get the following formula for the current moving in the x direction:

$$I_x = ntw(-v_x)(-e) \tag{5}$$

Where n is the charge carrier density, t is the thickness, and w is the width, e is the elementary charge. At the end of the day, by combining the equations 4 and 5 we get the hall voltage as

$$V_H = \frac{I_x B_z}{nte} \tag{6}$$

The hall coefficient is defined as

$$R_H = \frac{E_y}{j_x B_z} = \frac{1}{ne} [1] \tag{7}$$

where j is the current density.

However, the situation is more complicated in the case of a semiconductor, a material that exhibits properties in between a conductor and an isolator. Semiconductors in their natural state shows poor conductivity due to lack of free electrons. It is by the effect of doping that one can make a semiconductor to gain conductivity(see figure 2)[2]. If it is done by an electron acceptor it is p-type and by an electron donor then it is ntype.[3] In other words, in semiconductors, the charge carriers consists not only of a single type such as electrons, holes or ions, but there is a mixture of carriers. Semiconductors can be used in many areas by manipulating this feature. For example, they can be used in passing current in one direction more easily. Also, an electric field can be produced by combining n-type and p-type semiconductors.

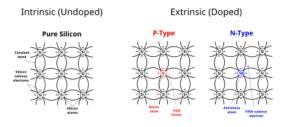

Fig. 2. Doping of a pure silicon [1]

Since the charge carriers do not solely consist of a single type anymore, the hole coefficient has a more complicated form:

$$R_H = \frac{n_h \mu_h^2 - n_e \mu_e^2}{e \left(n_h \mu_h + n_e \mu_e \right)^2} [4]$$
 (8)

 μ_h : the mobility of the hole μ_e : the mobility of the electron and by combining equations 6 and 7 we get:

$$R_H = \frac{V_H t}{IB} \tag{9}$$

If we have an n-type semiconductor, then we get the following expression for the mobility:

$$\mu_e = \frac{L}{AR_e n_e} = \frac{R_H L}{AR} \tag{10}$$

where A is the cross-section, L is length and R is the resistance.

II. METHOD

The following procedure was followed for the experiment:

- 1) The dimensions of the conductor is measured: Length: 16 ± 4mm (Current Direction), Width: 10 ± 1mm (Hall Voltage Direction), Thickness: 1.0 ± 0.2mm,
- 2) The resistance of the Hall probe is measured
- Hall voltage is measured at zero magnetic field to get a reference measurement
- Hall voltage is measured at constant but nonzero magnetic field
- 5) Hall voltage is measured at constant current, with the exactly same magnitude but both for positive and negative

III. THE EXPERIMENTAL SETUP

Here is the setup we have used in the experiment

- Helmholtz Coil
- Teslameter
- n-doped Germanium Hall Probe
- Power Supply
- Digital Multimeters
- Connecting leads
- Ruler

IV. THE DATA

For uncertainties of hall voltage, we have used the manual of the multimeter. Teslameter's uncertainty is $\pm \frac{5}{100}B$.[4] The rest has been taken to be the least significant figure.

V. THE ANALYSIS AND RESULTS

In the analysis, we have used the following error propagation formula if there is no correlation between the variables:[4] For the exact application of the formula in the analysis see the code in the appendix.

We have used the ROOT's built in function for getting linear fits and their corresponding results and errors.

$$\sigma_f = \sqrt{(\frac{\partial f}{\partial x})^2 (\sigma_x)^2 + (\frac{\partial f}{\partial y})^2 (\sigma_y)^2 + (\frac{\partial f}{\partial z})^2 (\sigma_z)^2 + \dots}$$
 (11)

Finding Resistance-Linefit

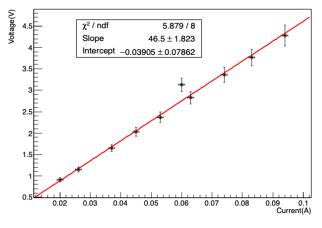

Fig. 6. Measurements for finding the resistance

The resistance was found out to be $46.5 \pm 1.8\Omega$.

Reference Measurements

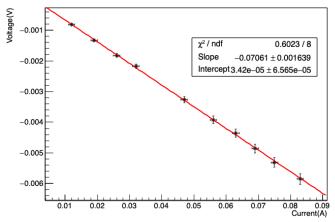

Fig. 7. Reference Measurements at B=0

B vs V_hall Measurements at I= 53mA

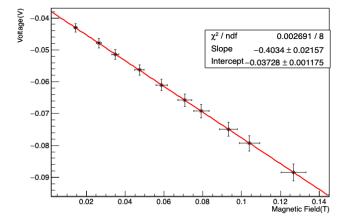

Fig. 9. Magnetic Field Measurements at I = 53mA

From figure(7) the offset equation is found out to be as:

$$V = -0.07061I + 3.42 * 10^{-5}$$
 (12)

For the positive constant current case the slope is found out to be: $-0.403\pm0.022\frac{V}{T}$. By using the equations 9 and 10, we get the $R_H=-0.00761\pm0.00158\frac{m^3}{As}$ and $\mu_e=-0.262\pm0.101\frac{m^2}{Vs}$ respectively.

I vs V_hall Measurements at B= 139.3 mT

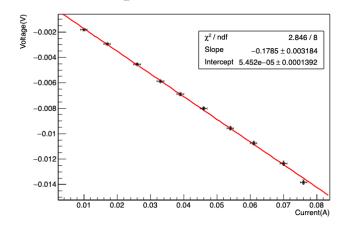

Fig. 8. The Varying Current Measurementsat B=139.3 mT

B vs V_hall Measurements at I= -53mA

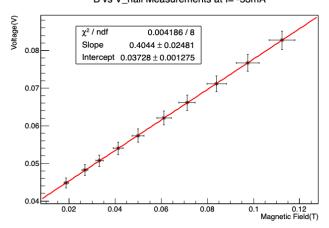

Fig. 10. Magnetic Field Measurements at I = -53mA

It is seen that the slope is found out to be: $-0.179\pm0.003\frac{V}{A}$. By using the equations 9 and 10, we get the $R_H=-0.00128\pm0.00027\frac{m^3}{As}$ and $\mu_e=-0.044\pm0.017\frac{m^2}{Vs}$ respectively.

Now for the negative constant current case the slope is found out to be: $0.404\pm0.025\frac{V}{T}.$ By using the equations 9 and 10, we get the $R_H=-0.00763\pm0.00160\frac{m^3}{As}$ and $\mu_e=-0.263\pm0.101\frac{m^2}{Vs}$ respectively.

The Measurements with Offset

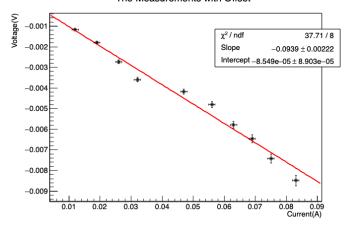

Fig. 11. The Varying Current Measurementsat B=139.3 mT with offset

Finally, by substracting the voltage values we get from the offset equation(12) from the nonzero constant magnetic field hall voltage measurements(figure 8), we found the slope as: $-0.094 \pm 0.002 \frac{V}{A}$. By using the equations 9 and 10, we get the $R_H = -0.00067 \pm 0.00014 \frac{m^3}{As}$ and $\mu_e = -0.023 \pm 0.009 \frac{m^2}{Vs}$ respectively.

Weighted Average Formula is:

$$\bar{x}_w = \frac{\sum_{i=1}^{N} \frac{x_i}{\sigma_i^2}}{\sum_{i=1}^{N} \frac{1}{\sigma_i^2}}$$
(13)

and the uncertainty in the Weighted Average:

$$\sigma_w = \sqrt{\frac{1}{\sum_{i=1}^{N} \frac{1}{\sigma_i^2}}} \tag{14}$$

To see how those formulas are applied see the code in the appendix. By using equations 13 and 14 we get the weighted averages of Hall Coefficient and Mobility of Electrons as:

$$R_H(weighted) = -0.00089 \pm 0.00012 \frac{m^3}{As}$$
 (15)

$$\mu_e(weighted) = -0.031 \pm 0.008 \frac{m^2}{Vs}$$
 (16)

VI. THE CONCLUSION

Hall voltage measurements at constant current seems to be a success due to their closeness to each other. Therefore, we have expected to get a similar result when we have corrected the measurements at constant nonzero magnetic field by subtracting the offset equation from the measured voltage values. This is required because the measurements in the nonzero constant magnetic field includes not only the hall effect voltage but also the V_{offset} values. In order to accomplish that, we have measured the hall voltage due only to the current itself so that we get an offset equation. On the other hand, our calculations indicate that we get the opposite effect that we have expected. In other words, our offset correction gave us Hall Coefficient and Mobility of Electron values not closer to the ones we got

in the constant current cases but the difference have increased. One final note might be that after applying the offset correction, our linefit intersects with the y-axis at point closer to the origin, as we want.

VII. APPENDIX

Here the code I have used in the analysis of the experiment. Codes also consist of the raw data. I chose to work with the raw data in the float forms inside the codes because of the small size of the data, namely 10 data pairs for each measurements and 5 different measurements in total.

```
double calculateVoltUncertainty(double V)
 = abs(V);
double error;
if (V <= 0.4)
error = (3 * V / 100);
else if (V \le 4)
error = (5 * V / 100) + 0.003;
else if (V \le 40)
error = (5 * V / 100) + 0.03;
else if (V <= 400)
error = (5 * V / 100) + 0.3;
else
error = (V / 100) + 4;
return error;
double t = 1e-3;
double t_error = 0.2e-3;
double L = 16e-3;
double L_error = 4e-3;
double w = 10e-3;
double w_error = 0.2e-3;
double A = w*t;
double A_error = sqrt(pow(w_error*t,2)+pow(w
*t_error, 2));
// PART 1
